Scientific Computation (SC) is the collection of tools, techniques, and theories that are required to solve problems in the field of science and engineering using computer-based mathematical models. The source data for scientific computation problems are usually from a data acquisition system which is used for conducting experiments in a laboratory setup. The large set of data across the entire function (such as time and temperature) in an experiment is usually complex to analyze and require segmenting and curve-fitting.

The purpose of this software is to develop a general purpose tool for fitting the experimental data across a 1D function to enable the data processing in a more simpler fashion. In other words, the software is intended to be used as a tool to fit the data and compute gradients. In this software, regression and interpolation are the two techniques used for data fitting.

Interested stakeholders in this project may include researchers in industrial and academic set-up, students, technicians and those who deal with processing of a large set of data to obtain critical information within a dataset. The processing encoded into the current software will be suitable for any scientific application which will require scientific data processing like obtaining a fit for the data, interpolating across the domain and computing gradients. This software can be run on a variety of personal desktop and laptop computers using Linux, Windows, or MacOS.
