Date	Version	Notes
Sep 28, 2018	1.0	First draft by Malavika
Date 2	1.1	Notes

2 Reference Material

This section records information for ease of reference. The information includes the units, symbols and abbreviations used in this document.

2.1 Table of Units

This library is designed to work for any set of data, irrespective of their units. So, table of units is not applicable.

2.2 Table of Symbols

The table that follows summarizes the symbols used in this document along with their units. The symbols are listed in alphabetical order. [I am just noting down symbols, they are not yet in alphabetical order —Malavika]

symbol	unit	description
A_{in}	m^2	
Φ		
$\sum_{min}^{max}$		

[ISSUE 1: For libraries, we have only mathematical symbols which do not have units. Should we remove units or just say not applicable. —Malavika] [Use your problems actual symbols. The si package is a good idea to use for units. —SS]

2.3 Abbreviations and Acronyms

symbol	description
A	Assumption
DD	Data Definition
GD	General Definition
GS	Goal Statement
IM	Instance Model
LC	Likely Change
PS	Physical System Description
R	Requirement
CA	Commonality Analysis
CFS	Curve Fitting Software
T	Theoretical Model

[Add any other abbreviations or acronyms that you add —SS]

Contents

3 Introduction

Scientific Computation (SC) is the collection of tools, techniques, and theories that are required to solve problems in the field of science and engineering using computer-based mathematical models. The source data for scientific computation problems are often large sets of data from experiments conducted in a laboratory setup. This large set of data (such as time and temperature) is usually complex to analyze and require segmenting and curve-fitting.

Curve fitting is the process of constructing a curve, or mathematical function, that has the best fit to a series of data points possibly subject to constraints Wiki.

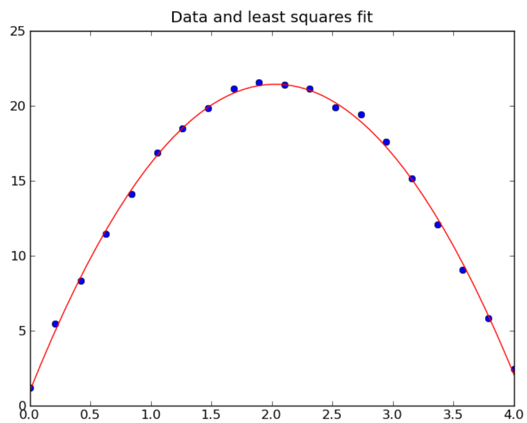

Figure 1: Typical example of a curve fitting process

A fit for the data can be obtained by different methods like interpolation, data smoothing and regression.

3.1 Interpolation

Interpolation is a process of fitting a function to given data so that the function has some values as the given data.

3.2 Smoothing

Smoothing is a process of creating an approximating function that attempts to capture important patterns in the data, while leaving out noise or other rapid phenomena.

3.3 Regression

Regression analysis is the process of finding the best fit parameters for a regression model for a given set of data points and thus obtain a curve through a set of data points.

3.4 Purpose of Document

3.5 Scope of the Family

3.6 Characteristics of Intended Reader

3.7 Organization of Document

4 General System Description

This section identifies the interfaces between the system and its environment, describes the potential user characteristics and lists the potential system constraints.

4.1 Potential System Contexts

[Your system context will likely include an explicit list of user and system responsibilities —SS]

- User Responsibilities:
  -
- CFS Responsibilities:
  - Detect data type mismatch, such as a string of characters instead of a floating point number
  -

4.2 Potential User Characteristics

The end user of CFS should have an understanding of undergraduate Level 1 Calculus and Physics.

4.3 Potential System Constraints

[You may not have any system constraints —SS]

5 Commonalities

5.1 Background Overview

5.2 Terminology and Definitions

This subsection provides a list of terms that are used in the subsequent sections and their meaning, with the purpose of reducing ambiguity and making it easier to correctly understand the requirements:

-

5.3 Data Definitions

This section collects and defines all the data needed to build the instance models. The dimension of each quantity is also given. [Modify the examples below for your problem, and add additional definitions as appropriate. —SS]

Number	DD1
Label	**Heat flux out of coil**
Symbol	q_C
SI Units	$\mathrm{W\,m^{-2}}$
Equation	$q_C(t) = h_C(T_C - T_W(t))$, over area A_C
Description	T_C is the temperature of the coil (°C). T_W is the temperature of the water (°C). The heat flux out of the coil, q_C ($\mathrm{W\,m^{-2}}$), is found by assuming that Newton's Law of Cooling applies (A**??**). This law (GD**??**) is used on the surface of the coil, which has area A_C ($\mathrm{m^2}$) and heat transfer coefficient h_C ($\mathrm{W\,m^{-2}\,°C^{-1}}$). This equation assumes that the temperature of the coil is constant over time (A**??**) and that it does not vary along the length of the coil (A**??**).

5.4 Goal Statements

Given the [inputs —SS], the goal statements are:

GS1: [One sentence description of the goal. There may be more than one. Each Goal should have a meaningful label. —SS]

5.5 Theoretical Models

This section focuses on the general equations and laws that CFS is based on. [Modify the examples below for your problem, and add additional models as appropriate. —SS]

Number	T1
Label	**Conservation of thermal energy**
Equation	$-\nabla \cdot \mathbf{q} + g = \rho C \frac{\partial T}{\partial t}$
Description	The above equation gives the conservation of energy for transient heat transfer in a material of specific heat capacity C ($\mathrm{J\,kg^{-1}\,{}^{\circ}C^{-1}}$) and density ρ ($\mathrm{kg\,m^{-3}}$), where $\mathbf{q}$ is the thermal flux vector ($\mathrm{W\,m^{-2}}$), g is the volumetric heat generation ($\mathrm{W\,m^{-3}}$), T is the temperature (°C), t is time (s), and ∇ is the gradient operator. For this equation to apply, other forms of energy, such as mechanical energy, are assumed to be negligible in the system (A**??**). In general, the material properties (ρ and C) depend on temperature.

6 Variabilities

6.1 Assumptions

A1: [Short description of each assumption. Each assumption should have a meaningful label. Use cross-references to identify the appropriate traceability to T, GD, DD etc., using commands like dref, ddref etc. —SS]

6.2 Calculation

6.3 Output

7 Requirements

This section provides the functional requirements, the business tasks that the software is expected to complete, and the nonfunctional requirements, the qualities that the software is expected to exhibit.

7.1 Functional Requirements

R1: [Requirements for the inputs that are supplied by the user. This information has to be explicit. —SS]

R2: [It isn't always required, but often echoing the inputs as part of the output is a good idea. —SS]

R3: [Calculation related requirements. —SS]

R4: [Verification related requirements. —SS]

R5: [Output related requirements. —SS]

7.2 Nonfunctional Requirements

[List your nonfunctional requirements. You may consider using a fit criterion to make them verifiable. —SS]

8 Likely Changes

LC1: [If there is a ranking of variabilities, or combinations of variabilities, that are more likely, this information can be included here. —SS]

9 Traceability Matrices and Graphs

[You will have to add tables. —SS]

10 Appendix

[Your report may require an appendix. For instance, this is a good point to show the values of the symbolic parameters introduced in the report. —SS]

10.1 Symbolic Parameters

[The definition of the requirements will likely call for SYMBOLIC_CONSTANTS. Their values are defined in this section for easy maintenance. —SS]

[Points to be noted —Malavika]
[** —Malavika]
[Interpolation means fitting some function to given data so that the function has some values as the given data. —Malavika]
The Simplest 1d interpolation is given by:
for a given data (t_i, y_i), where $i = 1, 2, 3...m$,
f is an interpolating function such that,

$$f(t_i) = y_i \text{where i} = 1, 2...m$$

Some of the variabilities includes:

- What form should the function have?
- How should the function behave between data points?
- Should the function inherit properties of the data such as monotonicity, convexity or periodicity?
- Are we interested in the values of the parameters that define the interpolating function, or simply in evaluating the function at various points for plotting or other purposes?
- If the function and data are plotted, should the results be visually pleasing?

11 Selection of function

The selection of function for interpolation depends on the following factors:

- How easy is the interpolant or the function is to work with. Working means determining the parameters of the interpolant from the data, evaluating the interpolant at a given point, differentiating or integrating the interpolant.
- How well the properties of the interpolant match the properties of the data to be fit(smoothness, monotonicity, convexity, periodicity etc)

Some of the familiar functions commonly used for interpolation are:

- Polynomials
- Piecewise Polynomials
- Trignometric functions
- Exponential functions
- Rational functions

[Questions: Ask Dr.Smith if we need to have all these five variabilities for fitting data or its enough if we have piecewise and polynomial —Malavika]

To find an interpolating function for a set of data points, it is important to make sure that the interpolant exists. This comes down to the discussion of matching the number of parameters in the interpolant to number of data points to be fit.If there are too few parameters, then the interpolant does not exist. If there are too many points, then the interpolant is not unique.

For a gien set of data points (t_i, y_i), where i $= 1, 23...m$, an interpolant is chosen from a suitable set of basis functions $\Phi(t), \Phi_1(t), ...\Phi_n(t)$. Therefore, the interpolating function f can be expressed as a linear combination of these basis functions.

$$f(t) = \sum_{j=1}^{n} x_j \Phi_j(t)$$

where x_j are the parameters to be found. But inorder for f to be interpolating the data points (t_i, y_i),

$$f(t_i) = \sum_{j=1}^{n} x_j \Phi_j(t) = y_i$$

where i $= 1, 2, 3...m$ This can be expressed as a liner system of equations

$$Ax = y$$

where A is the basis matrix whose m X n entries are given by,

$$a_{ij} = \Phi_j(t_i)$$

where a_{ij} is the value of j^{th} basis function at i^{th} data point.

11.1 For my understanding

[Important points to be noted here —Malavika]

- m data points (t_i, y_i) where $i = 1....m$

- n basis function $\Phi_1(t), \Phi_2(t), \Phi_3(t)...\Phi_n(t)$
- f is the interpolating function
- f is the linear combination of basis function as shown below
- $$f(t_i) = \sum_{j=1}^{n} x_j \Phi_j(t) = y_i$$
- x_j is the parameters of the fit to be found

11.2 Polynomial interpolation

Polynomial function has different types of basis functions.

- Monomial
- Lagrange
- Newton
- Orthogonal
- Interpolating continuous functions

11.2.1 Monomial basis

To interpolate n data points, we choose k = n-1 as the maximum degree of the polynomial. We define P_{n-1} as the set of polynomials of degree at most n-1 and is composed on first n monomials.

$$\Phi_j(t) = t^{j-1}$$

where j $= 1, 2, ...n$ We can construct the polynomial from this which will have the form,

$$P_{n-1}(t) = x_1 + x_2 t + x_3 t^2 + x_4 t^3 + ...x_n t^{n-1}$$

The matrix form is given by,

$$Ax = \begin{bmatrix} 1 & t_1 & t_1^2 & \dots & t_1^{n-1} \\ 1 & t_2 & t_2^2 & \dots & t_2^{n-1} \\ \vdots & \vdots & \vdots & \vdots & \\ 1 & t_n & t_n^2 & \dots & t_n^{n-1} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} = y$$

[Note: A matrix whose columns are successive powers of some independent variable t is called Vandermonde matrix —Malavika] [Assumption: The vandermonde matrix should be non singular provided t_i are all distint, hence the interpolant exists. —Malavika] [Cost of computing interpolant is high —Malavika]

11.3 Lagrange Interpolation

For a given set of data points (t_i, y_i), $i = 1, 2, \ldots$ n, the Lagrange polynomial of degree n-1, P_{n-1} is given by,

$$P_{n-1}(t) = y_1 l_1(t) + y_2 l_2(t) + \ldots y_n l_n(t).$$

where the basis functions(also called fundamental polynomials) for the l_j is given by,

$$l_j(t) = \frac{\Pi_{k=1,k\neq j}^{n}(t - t_k)}{\Pi_{k=1,k\neq j}^{n}(t_j - t_k)} = \frac{(t - t_1)}{(t_j - t_1)} \ldots \frac{(t - t_{j-1})}{(t_j - t_{j-1})} \frac{(t - t_{j+1})}{(t_j - t_{j+1})} \ldots \frac{(t - t_n)}{(t_j - t_n)}$$

where j $=1, 2, \ldots n$ [Expensive to evaluate and more difficult to differentiate and integrate —Malavika]

11.4 Newton Interpolation

For a given set of data points (t_i, y_i), $i = 1, 2, \ldots$ n, the newton basis function for P_{n-1} is given by,

$$\pi(t) = \Pi_{k=1}^{j-1}(t - t_k)$$

where j = 1,2,....n,

The polynomial P_{n-1} is given by,

$$P_{n-1}(t) = x_1 + x_2(t - t_1) + x_3(t - t_1)(t - t_2) + \ldots x_n(t - t_1)(t - t_2)\ldots(t - t_{n-1})$$

[** —Malavika]
